Plastic Pollution

A Global Crisis

Our planet faces an unprecedented environmental emergency. Over 8 million tonnes of plastic enter waterways annually, choking ecosystems and threatening all life.

The Problem on Our Campus

Event Aftermath

Plastic waste builds up rapidly after campus gatherings, overwhelming waste systems and leaving debris across lawns and walkways.

Water Contamination

Wind and rainfall carry waste into local drains and canals, transporting plastic into nearby aquatic ecosystems we depend on.

Microplastic Threat

Degrading plastics fragment into microplastics, contaminating campus soil and water systems. Science Advances (2022) confirms their presence in local environments.

A Threat to Our Campus Ecosystem

- **Organism Harm**

  Microplastics threaten aquatic and soil organisms, disrupting reproductive cycles and immune systems (Environmental Science & Technology, 2023).

- **Wildlife Mortality**

  Birds, fish, and mammals mistake plastic for food. Ingestion causes internal injuries, starvation, and death (WWF, 2023).

- **Accelerating Crisis**

  Without action, pollution worsens each semester, compounding damage and reducing nature's capacity to recover.
